TikTok Project

Recall that you are a data professional at TikTok. Your supervisor was impressed with the work you have done and has requested that you build a machine learning model that can be used to determine whether a video contains a claim or whether it offers an opinion. With a successful prediction model, TikTok can reduce the backlog of user reports and prioritize them more efficiently.

project: Classifying videos using machine learning

In this activity, you will practice using machine learning techniques to predict on a binary outcome variable.

The purpose of this model is to mitigate misinformation in videos on the TikTok platform.

The goal of this model is to predict whether a TikTok video presents a "claim" or presents an "opinion".

This activity has three parts:

Part 1: Ethical considerations

- · Consider the ethical implications of the request
- Should the objective of the model be adjusted?

Part 2: Feature engineering

• Perform feature selection, extraction, and transformation to prepare the data for modeling

Part 3: Modeling

Build the models, evaluate them, and advise on next steps

Follow the instructions and answer the questions below to complete the activity. Then, you will complete an Executive Summary using the questions listed on the PACE Strategy Document.

Be sure to complete this activity before moving on. The next course item will provide you with a completed exemplar to compare to your own work.

Classify videos using machine learning

description has

been provided PACE stages

for this image

Throughout these project notebooks, you'll see references to the problem-solving framework PACE. The following notebook components are labeled with the respective PACE stage: Plan, Analyze, Construct, and Execute.

No

description has Pace: Plan been provided

for this image Consider the questions in your PACE Strategy Document to reflect on the Plan stage.

In this stage, consider the following questions:

- 1. What are you being asked to do? What metric should I use to evaluate success of my business/organizational objective?
- 2. What are the ethical implications of the model? What are the consequences of your model making errors?
- What is the likely effect of the model when it predicts a false negative (i.e., when the model says a video does not contain a claim and it actually does)?
- What is the likely effect of the model when it predicts a false positive (i.e., when the model says a video does contain a claim and it actually does not)?
- 3. How would you proceed?

Exemplar responses:

1. What are you being asked to do?

Business need and modeling objective

TikTok users can report videos that they believe violate the platform's terms of service. Because there are millions of TikTok videos created and viewed every day, this means that many videos get reported—too many to be individually reviewed by a human moderator.

Analysis indicates that when authors do violate the terms of service, they're much more likely to be presenting a claim than an opinion. Therefore, it is useful to be able to determine which videos make claims and which videos are opinions.

TikTok wants to build a machine learning model to help identify claims and opinions. Videos that are labeled opinions will be less likely to go on to be reviewed by a human moderator. Videos that are labeled as claims will be further sorted by a downstream process to determine whether they should get prioritized for review. For example, perhaps videos that are classified as claims would then be ranked by how many times they were reported, then the top x% would be reviewed by a human each day.

A machine learning model would greatly assist in the effort to present human moderators with videos that are most likely to be in violation of TikTok's terms of service.

Modeling design and target variable

The data dictionary shows that there is a column called claim_status. This is a binary value that indicates whether a video is a claim or an opinion. This will be the target variable. In other words, for each video, the model should predict whether the video is a claim or an opinion.

This is a classification task because the model is predicting a binary class.

Select an evaluation metric

To determine which evaluation metric might be best, consider how the model might be wrong. There are two possibilities for bad predictions:

- False positives: When the model predicts a video is a claim when in fact it is an opinion
- False negatives: When the model predicts a video is an opinion when in fact it is a claim
- 2. What are the ethical implications of building the model? In the given scenario, it's better for the model to predict false positives when it makes a mistake, and worse for it to predict false negatives. It's very important to identify videos that break the terms of service, even if that means some opinion videos are misclassified as claims. The worst case for an opinion misclassified as a claim is that the video goes to human review. The worst case for a claim that's misclassified as an opinion is that the video does not get reviewed and it violates the terms of service. A video that violates the terms of service would be considered posted from a "banned" author, as referenced in the data dictionary.

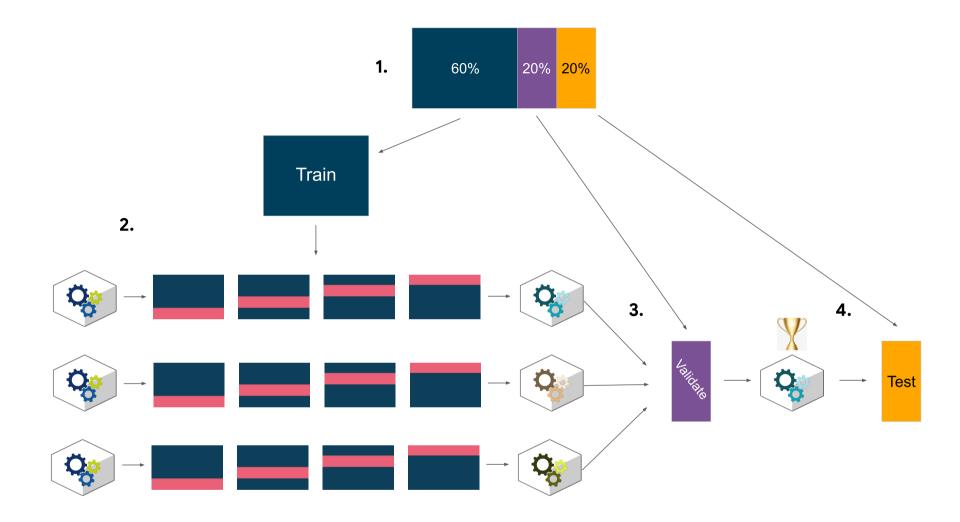

Because it's more important to minimize false negatives, the model evaluation metric will be recall.

3. How would you proceed?

Modeling workflow and model selection process

Previous work with this data has revealed that there are ~20,000 videos in the sample. This is sufficient to conduct a rigorous model validation workflow, broken into the following steps:

- 1. Split the data into train/validation/test sets (60/20/20)
- 2. Fit models and tune hyperparameters on the training set
- 3. Perform final model selection on the validation set
- 4. Assess the champion model's performance on the test set

Task 1. Imports and data loading

Start by importing packages needed to build machine learning models to achieve the goal of this project.

```
In [3]: # Import packages for data manipulation
import pandas as pd
import numpy as np

# Import packages for data visualization
import matplotlib.pyplot as plt
import seaborn as sns
# Import packages for data preprocessing
```

```
# Import packages for data modeling
from sklearn.model_selection import train_test_split, GridSearchCV
from sklearn.metrics import classification_report, accuracy_score, precision_score, \
recall_score, f1_score, confusion_matrix, ConfusionMatrixDisplay

from sklearn.ensemble import RandomForestClassifier
from xgboost import XGBClassifier
from xgboost import plot_importance
```

Load the data from the provided csv file into a dataframe.

Note: As shown in this cell, the dataset has been automatically loaded in for you. You do not need to download the .csv file, or provide more code, in order to access the dataset and proceed with this lab. Please continue with this activity by completing the following instructions.

In [4]: # Load dataset into dataframe
data = pd.read_csv("tiktok_dataset.csv")

No
description has been provided
for this image

Consider the questions in your PACE Strategy Document to reflect on the Analyze stage.

Task 2: Examine data, summary info, and descriptive stats

Inspect the first five rows of the dataframe.

In [5]:		splay first f head()	ew rows

Check for and handle missing values

```
In [9]: # Check for missing values
data.isna().sum()
```

Out[9]: # claim status 298 video_id video duration sec video_transcription_text verified status author ban status video view count 298 video_like_count 298 video_share_count 298 video download count 298 video_comment_count 298 dtype: int64

Exemplar response: There are very few missing values relative to the number of samples in the dataset. Therefore, observations with missing values can be dropped.

```
data = data.dropna(axis=0)
```

Check for and handle duplicates

```
In [11]: # Check for duplicates
         data.duplicated().sum()
```

Out[11]: 0

Exemplar response: There are no duplicate observations in the data.

Check for and handle outliers

Exemplar response: Tree-based models are robust to outliers, so there is no need to impute or drop any values based on where they fall in their distribution.

Check class balance.

```
In [12]: # Check class balance
         data["claim_status"].value_counts(normalize=True)
```

Out[12]: claim_status

claim 0.503458 opinion 0.496542

Name: proportion, dtype: float64

Exemplar response: Approximately 50.3% of the dataset represents claims and 49.7% represents opinions, so the outcome variable is balanced.

description has PACE: Construct

for this image Consider the questions in your PACE Strategy Document to reflect on the Construct stage.

Task 3. Feature engineering

Extract the length (character count) of each video_transcription_text and add this to the dataframe as a new column called text_length so that it can be used as a feature in the model.

```
In [13]: # Create `text_length` column
         data['text_length'] = data['video_transcription_text'].str.len()
         data.head()
```

Out[13]:	#	claim_status	video_id	video_duration_sec	video_transcription_text	verified_status	author_ban_status	video_view_count	video_like_count	video_share_count	$video_download_count$	$video_comment_count$	text_length
	0 1	l claim	7017666017	59	someone shared with me that drone deliveries a	not verified	under review	343296.0	19425.0	241.0	1.0	0.0	97
	1 2	2 claim	4014381136	32	someone shared with me that there are more mic	not verified	active	140877.0	77355.0	19034.0	1161.0	684.0	107
	2 3	3 claim	9859838091	31	someone shared with me that american industria	not verified	active	902185.0	97690.0	2858.0	833.0	329.0	137
	3 4	4 claim	1866847991	25	someone shared with me that the metro of st. p	not verified	active	437506.0	239954.0	34812.0	1234.0	584.0	131
	4 5	5 claim	7105231098	19	someone shared with me that the number of busi	not verified	active	56167.0	34987.0	4110.0	547.0	152.0	128

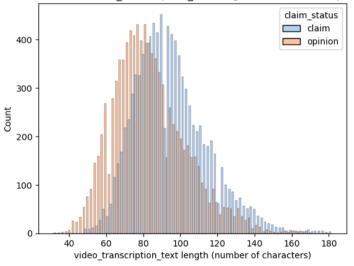

Calculate the average text_length for claims and opinions.

82.722562

opinion

Visualize the distribution of text length for claims and opinions using a histogram.

Distribution of video transcription text length for claims and opinions

Letter count distributions for both claims and opinions are approximately normal with a slight right skew. Claim videos tend to have more characters—about 13 more on average, as indicated in a previous cell.

Feature selection and transformation

Encode target and catgorical variables.

```
In [16]: X = data.copy()
# Drop unnecessary columns
X = X.drop(['#', 'video_id'], axis=1)
# Encode target variable
X['claim_status'] = X['claim_status'].replace({'opinion': 0, 'claim': 1})
# Dummy encode remaining categorical values
X = pd.get_dummies(X,
```

```
columns=['verified_status', 'author_ban_status'],
                              drop first=True)
          X.head()
Out[16]:
             claim_status video_duration_sec video_transcription_text video_view_count video_like_count video_share_count video_download_count video_comment_count text_length verified_status_verified author_ban_status_banned
                                         someone shared with me
                                                                                                                                                                                 97

Task 4. Split the data

Assign target variable.

Exemplar response: In this case, the target variable is claim_status.

- 0 represents an opinion
- 1 represents a claim

```
In [17]: # Isolate target variable
         y = X['claim_status']
```

Isolate the features.

```
In [18]: # Isolate features
         X = X.drop(['claim_status'], axis=1)
         # Display first few rows of features dataframe
        X.head()
```

Task 5: Create train/validate/test sets

Split data into training and testing sets, 80/20.

In [19]: # Split the data into training and testing sets
X_tr, X_test, y_tr, y_test = train_test_split(X, y, test_size=0.2, random_state=0)

Split the training set into training and validation sets, 75/25, to result in a final ratio of 60/20/20 for train/validate/test sets.

In [20]: # Split the training data into training and validation sets
X_train, X_val, y_train, y_val = train_test_split(X_tr, y_tr, test_size=0.25, random_state=0)

Confirm that the dimensions of the training, validation, and testing sets are in alignment.

In [21]: # Get shape of each training, validation, and testing set
X_train.shape, X_val.shape, X_test.shape, y_train.shape, y_val.shape, y_test.shape

Out[21]: ((11450, 11), (3817, 11), (3817, 11), (11450,), (3817,), (3817,))

Exemplar notes:

- The number of features (11) aligns between the training and testing sets.
- The number of rows aligns between the features and the outcome variable for training (11,450) and both validation and testing data (3,817).

BONUS CONTENT - Tokenize text column

NOTE: You are not expected to do this or know this, but you might find it useful and/or interesting to understand some basic ideas behind natural language processing (NLP), because of the nature of the data provided in this TikTok project.

The feature video_transcription_text is text-based. It is not a categorical variable, since it does not have a fixed number of possible values. One way to extract numerical features from it is through a bag-of-words algorithm like CountVectorizer.

CountVectorizer works by splitting text into n-grams, which are groups of n consecutive words. For instance, "a dime for a cup of coffee" (phrase A) broken into 2-grams would result in six two-word combinations:

a dime | dime for | for a | a cup | cup of | of coffee |

Then, the next sample's text would be parsed into 2-grams. So, "ask for a cup for a child" (phrase B) would result in:

ask for | for a | a cup | cup for | for a | a child |

This process would repeat for each observation in the dataset, and each n-gram would be treated like a distinct feature. Then, the text of each observation is compared to the full array of n-grams, and the numbers of occurrences are tallied:

	a dime	dime for	for a	a cup	cup of	of coffee	ask for	cup for	a child
phrase A	1	1	1	1	1	1	0	0	0
phrase B	0	0	2	1	1	0	1	1	1
TOTAL	1	1	3	2	2	1	1	1	1

This would happen for the text of each observation in the data, and the text of each observation is parsed to get tallies for all the 2-word phrases from the entire data set for each observation, creating a large matrix.

If text is broken into 1-grams, then each feature in the matrix is an individual word.

After the count matrix has been created, CountVectorizer lets you the choose to keep only the most frequently occurring n-grams. You specify how many. The n-grams that you select can then be used as features in a model.

Splitting text into n-grams is an example of tokenization. Tokenization is the process of breaking text into smaller units to derive meaning from the resulting tokens.

This notebook breaks each video's transcription text into both 2-grams and 3-grams, then takes the 15 most frequently occurring tokens from the entire dataset to use as features.

```
In [22]: # Set up a `CountVectorizer` object, which converts a collection of text to a matrix of token counts
          count vec = CountVectorizer(ngram range=(2, 3),
                                      max_features=15,
                                      stop words='english')
          count_vec
                                          CountVectorizer
         CountVectorizer(max features=15, ngram range=(2, 3), stop words='english')
          Fit the vectorizer to the training data (generate the n-grams) and transform it (tally the occurrences). Only fit to the training data, not the validation or test data.
In [23]: # Extract numerical features from `video_transcription_text` in the training set
          count data = count vec.fit transform(X train['video transcription text']).toarray()
          count_data
Out[23]: array([[0, 0, 0, ..., 0, 0, 0],
                 [0, 0, 0, \ldots, 0, 0, 0],
                 [0, 0, 0, ..., 0, 0, 0],
                 [0, 0, 1, \ldots, 1, 0, 0],
                 [0, 0, 0, ..., 0, 0, 0],
                 [0, 0, 0, ..., 0, 0, 0]])
In [24]: # Place the numerical representation of `video transcription text` from training set into a dataframe
          count_df = pd.DataFrame(data=count_data, columns=count_vec.get_feature_names_out())
          # Display first few rows
         count_df.head()

Task 6. Build models

Build a random forest model

Fit a random forest model to the training set. Use cross-validation to tune the hyperparameters and select the model that performs best on recall.

```
# Define a dictionary of scoring metrics to capture
scoring = {'accuracy', 'precision', 'recall', 'f1'}
# Instantiate the GridSearchCV object
rf_cv = GridSearchCV(rf, cv_params, scoring=scoring, cv=5, refit='recall')
```

Note this cell might take several minutes to run.

```
In [31]: %%time
         rf_cv.fit(X_train_final, y_train)
        CPU times: user 5min 37s, sys: 584 ms, total: 5min 37s
        Wall time: 5min 37s
                       GridSearchCV
Out[31]: •
          ▶ estimator: RandomForestClassifier
                ▶ RandomForestClassifier
In [32]: # Examine best recall score
         rf_cv.best_score_
Out[32]: 0.9948228253467271
In [33]: # Examine best parameters
         rf_cv.best_params_
Out[33]: {'max depth': None,
           'max features': 0.6,
           'max samples': 0.7,
           'min_samples_leaf': 1,
           'min_samples_split': 2,
           'n estimators': 200}
```

Exemplar response:

This model performs exceptionally well, with an average recall score of 0.995 across the five cross-validation folds. After checking the precision score to be sure the model is not classifying all samples as claims, it is clear that this model is making almost perfect classifications.

Build an XGBoost model

Note this cell might take several minutes to run.

```
In [35]: %%time
          xgb_cv.fit(X_train_final, y_train)
        CPU times: user 9min 49s, sys: 2.06 s, total: 9min 51s
        Wall time: 5min 1s
                   GridSearchCV
Out[35]: •
           • estimator: XGBClassifier
                  XGBClassifier
In [36]: xgb_cv.best_score_
Out[36]: 0.9906808769992594
In [37]: xgb_cv.best_params_
Out[37]: {'learning rate': 0.1,
           'max_depth': 4,
           'min child weight': 5,
           'n_estimators': 300}
          Exemplar response:
          This model also performs exceptionally well. Although its recall score is very slightly lower than the random forest model's, its precision score is perfect.
```

Task 7. Evaluate models

Evaluate models against validation data.

Random forest

```
In [38]: # Use the random forest "best estimator" model to get predictions on the validation set
        y_pred = rf_cv.best_estimator_.predict(X_val_final)
         Display the predictions on the validation set.
```

```
In [39]: # Display the predictions on the validation set
         y_pred
```

```
Out[39]: array([1, 0, 1, ..., 1, 1, 1])
```

Display the true labels of the validation set.

```
In [40]: # Display the true labels of the validation set
         y_val
```

```
Out[40]: 5846
        12058
               0
        2975
        8432
               1
        6863
               1
        6036

        6544
               1
        2781
               1
        6426
               1
        4450
               1
        Name: claim_status, Length: 3817, dtype: int64
```

Create a confusion matrix to visualize the results of the classification model.

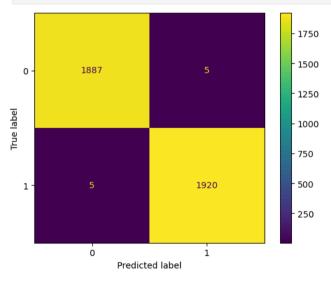

```
In [41]: # Create a confusion matrix to visualize the results of the classification model
```

```
# Compute values for confusion matrix
log_cm = confusion_matrix(y_val, y_pred)

# Create display of confusion matrix
log_disp = ConfusionMatrixDisplay(confusion_matrix=log_cm, display_labels=None)

# Plot confusion matrix
log_disp.plot()

# Display plot
plt.show()
```

Exemplar notes:

The upper-left quadrant displays the number of true negatives: the number of opinions that the model accurately classified as so.

The upper-right quadrant displays the number of false positives: the number of opinions that the model misclassified as claims.

The lower-left quadrant displays the number of false negatives: the number of claims that the model misclassified as opinions.

The lower-right quadrant displays the number of true positives: the number of claims that the model accurately classified as so.

A perfect model would yield all true negatives and true positives, and no false negatives or false positives.

As the above confusion matrix shows, this model does not produce any false negatives.

Create a classification report that includes precision, recall, f1-score, and accuracy metrics to evaluate the performance of the model.

Note: In other labs there was a custom-written function to extract the accuracy, precision, recall, and F₁ scores from the GridSearchCV report and display them in a table. You can also use scikit-learn's built-in classification_report() function to obtain a similar table of results.

```
In [42]: # Create a classification report
# Create classification report for random forest model
target_labels = ['opinion', 'claim']
print(classification_report(y_val, y_pred, target_names=target_labels))

precision recall f1-score support

opinion 1.00 1.00 1.00 1.00 1.00 1.925

accuracy 1.00 3817
macro avg 1.00 1.00 1.00 3817
weighted avg 1.00 1.00 1.00 3817
```

Exemplar response:

The classification report above shows that the random forest model scores were nearly perfect. The confusion matrix indicates that there were 10 misclassifications—five false postives and five false negatives.

XGBoost

Now, evaluate the XGBoost model on the validation set.

```
In [43]: #Evaluate XGBoost model
y_pred = xgb_cv.best_estimator_.predict(X_val_final)

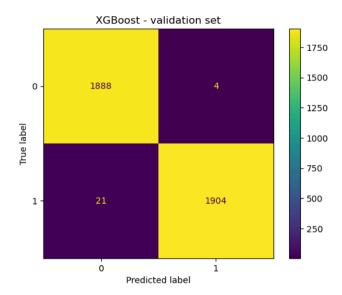

In [44]: y_pred

Out[44]: array([1, 0, 1, ..., 1, 1, 1])

In [45]: # Compute values for confusion matrix
log_cm = confusion_matrix(y_val_, y_pred)

# Create display of confusion matrix
log_disp = Confusion matrix
log_disp.plet()

# Display plot
plt.title('XGBoost - validation set');
plt.show()
```

```
In [46]: # Create a classification report
        target labels = ['opinion', 'claim']
        print(classification_report(y_val, y_pred, target_names=target_labels))
                  precision recall f1-score support
          opinion
                      0.99
                            1.00
                                       0.99
                                               1892
                      1.00 0.99 0.99
                                               1925
            claim
          accuracy
                                       0.99
                                               3817
         macro avg
                      0.99 0.99 0.99
                                               3817
                      0.99 0.99 0.99
                                               3817
      weighted avg
```

Exemplar response:

The results of the XGBoost model were also nearly perfect. However, its errors tended to be false negatives. Identifying claims was the priority, so it's important that the model be good at capturing all actual claim videos. The random forest model has a better recall score, and is therefore the champion model.

Use champion model to predict on test data

Both random forest and XGBoost model architectures resulted in nearly perfect models. Nonetheless, in this case random forest performed a little bit better, so it is the champion model.

Now, use the champion model to predict on the test data.

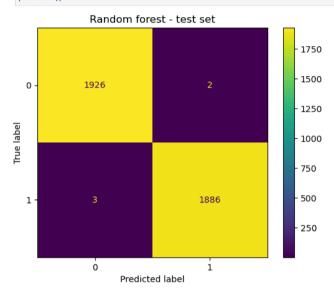

```
In [47]: # Use champion model to predict on test data
y_pred = rf_cv.best_estimator_.predict(X_test_final)

In [48]: # Compute values for confusion matrix
log_cm = confusion_matrix(y_test, y_pred)

# Create display of confusion matrix
log_disp = ConfusionMatrixDisplay(confusion_matrix=log_cm, display_labels=None)

# Plot confusion matrix
log_disp.plot()
```

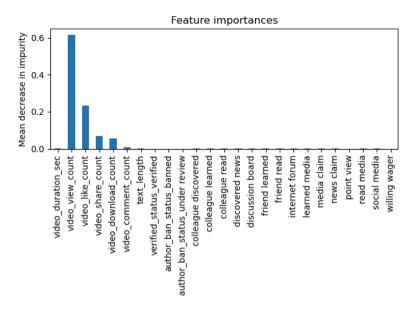

```
# Display plot
plt.title('Random forest - test set');
plt.show()
```

Feature importances of champion model

```
importances = rf_cv.best_estimator_.feature_importances_
    rf_importances = pd.Series(importances, index=X_test_final.columns)

fig, ax = plt.subplots()
    rf_importances.plot.bar(ax=ax)
    ax.set_title('Feature importances')
    ax.set_ylabel('Mean decrease in impurity')
    fig.tight_layout()
```

Exemplar response:

The most predictive features all were related to engagement levels generated by the video. This is not unexpected, as analysis from prior EDA pointed to this conclusion.

Conclusion

In this step use the results of the models above to formulate a conclusion. Consider the following questions:

- 1. Would you recommend using this model? Why or why not?
- 2. What was your model doing? Can you explain how it was making predictions?
- 3. Are there new features that you can engineer that might improve model performance?
- 4. What features would you want to have that would likely improve the performance of your model?

Remember, sometimes your data simply will not be predictive of your chosen target. This is common. Machine learning is a powerful tool, but it is not magic. If your data does not contain predictive signal, even the most complex algorithm will not be able to deliver consistent and accurate predictions. Do not be afraid to draw this conclusion.

Exemplar response:

1. Would you recommend using this model? Why or why not?

Yes, one can recommend this model because it performed well on both the validation and test holdout data. Furthermore, both precision and F₁ scores were consistently high. The model very successfully classified claims and opinions.

- 2. *What was your model doing? Can you explain how it was making predictions?* The model's most predictive features were all related to the user engagement levels associated with each video. It was classifying videos based on how many views, likes, shares, and downloads they received. 3. *Are there new features that you can engineer that might improve model performance?* Because the model currently performs nearly perfectly, there is no need to engineer any new features.

 4. *What features would you want to have that would likely improve the performance of your model?* The current version of the model does not need any new features. However, it would be helpful to have the number of times the video was
- reported. It would also be useful to have the total number of user reports for all videos posted by each author.
